

Security Analyst 22.2

Release Notes

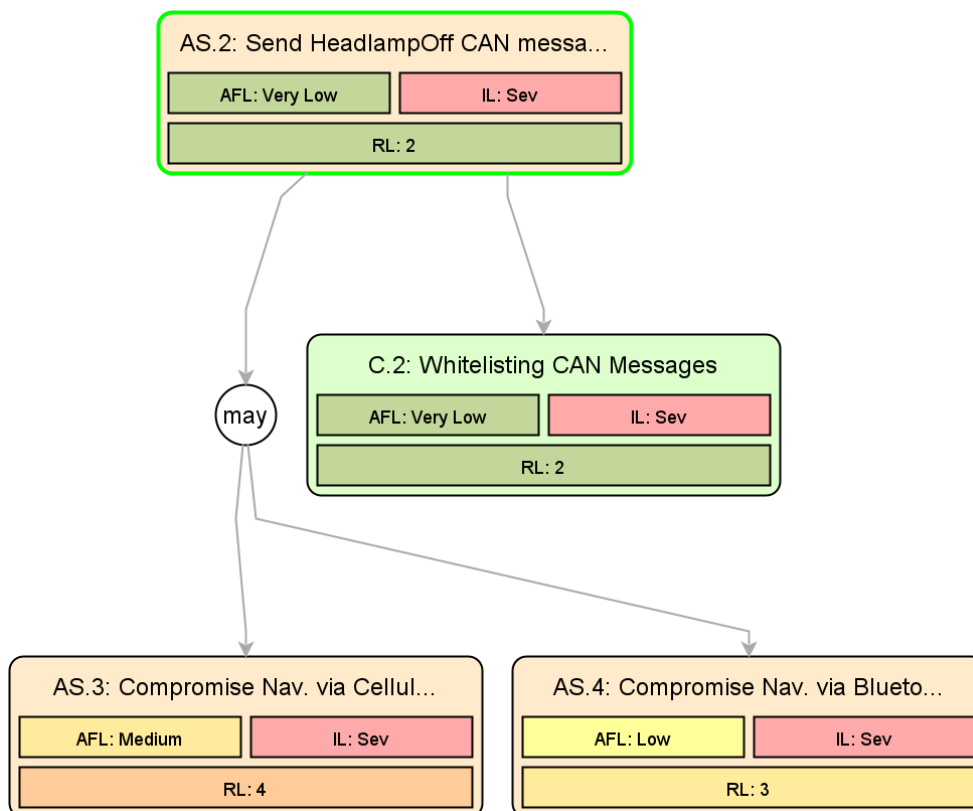

Local Risk Level	2
Item Definition & Analysis Excel Import	3
Extended Impact Factors	4
Multiple Feasibility Models	5
Impact Levels per Stakeholder	6
Custom Factors	7
Various fixes and improvements	8
Version Mapping	9

Local Risk Level

In the attack tree and all editors that concern attack steps, controls or threat scenarios, the display of the well known triplet of feasibility, impact and corresponding risk has changed. Now, Security Analyst highlights the local rating and makes sure that the triplets adhere to the configured risk matrix.

You might wonder what local means. If you take a look at AS.3 in the following example, which is an excerpt of the ISO/SAE 21434 headlamp example, you'll notice that the displayed risk level has changed and no longer takes into account the implemented control up in the attack tree. Instead, a consistent triplet is shown which leads to less confusion.

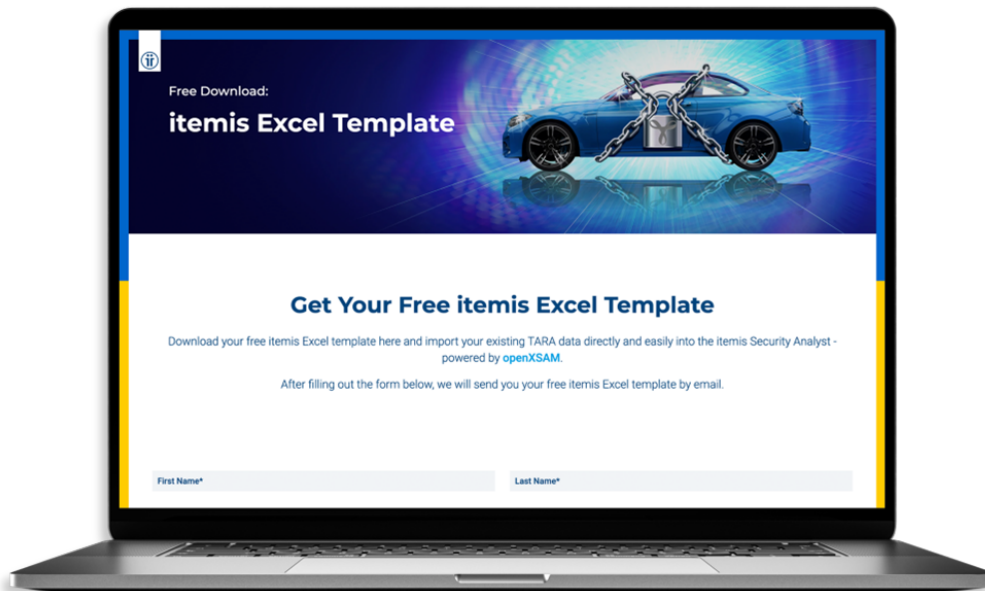

If the global risk level is of interest, just walk up the attack tree and take a look at the calculated risk at the related attack steps or fast forward to the threat scenario.

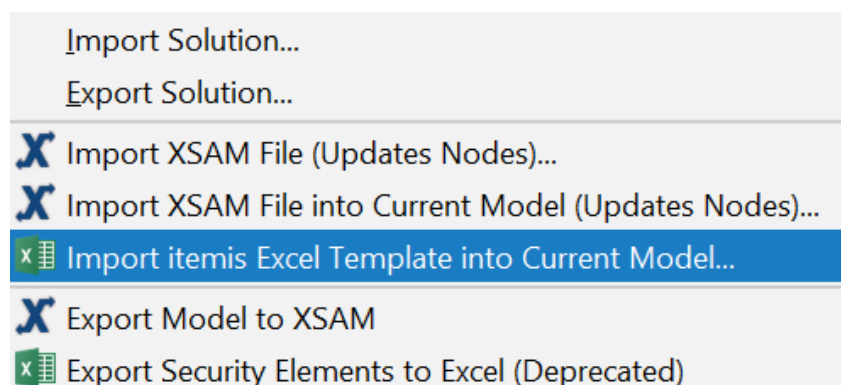

Note: This does just change the displayed values. We are not sacrificing precision when calculating the risk.

Item Definition & Analysis Excel Import

Based on openXSAM and our experience with the ISO/SAE 21434 model, we have designed our itemis Excel template that can be used to exchange TARA data without the need for learning any XML syntax. The template is still evolving, you may download the most recent version already now via the following [download page](#).

You can import the file into the currently selected TARA model via the following menu entry. Please note that as of now, only the item definition and security analysis import is supported. Method configuration and catalogs are yet to come. Furthermore, make sure that your method configuration and catalog are compatible. Hint: Creating a new empty ISO/SAE 21434 project takes care of this.

Privacy note: The itemis Excel template import is powered by the itemis cloud.

Extended Impact Factors

Impact Categories can now be marked as *hidden* in the inspector, which hides these categories in the Risk Level Tables, e.g. in the Threat Scenarios.

A new Impact aggregator was added which aggregates Impact Options per stakeholder e.g. MAX aggregation for Stakeholder RU and SUM aggregation for Stakeholder OEM. This new feature is configured in the Risk Model.

Impact Combinators

Stakeholder specific: Aggregate per Stakeholder

for stakeholder RU

default aggregation of impact options (maximal impact)

for stakeholder OEM

aggregation of impact options (sum of impact)

for other stakeholders:

default aggregation of impact options (maximal impact)

Impact Scaling was changed from int to double, to allow more precise scaling.

Furthermore, the standard MAX and SUM aggregators now have the option to ignore the impact scaling. This can be configured in the inspector of the aggregators.

Note: This is not required by the ISO/SAE 21434 and is an advanced feature for complex method configurations. For most Security Analyst users, we recommend keeping the configuration simple and starting with a common impact aggregator for all declared stakeholders.

Multiple Feasibility Models

To make it easier to model different threat agents, Security Analyst now supports multiple feasibility models per TARA. These feasibility Models have their own set of Categories and Options.

Attack Steps, Threat Classes, Controls and Control Classes now allow you to choose a Feasibility. If there are multiple feasibility models available, one can be selected for Attack Steps and Controls to be active, or they can be derived from the respective class.

Attack Step AS.1: Spoofing - CAN Bus

<no description> [Edit](#)

IL	RU. Severe
AFL	Low
RL	3

{

Instantiates TC.1: Spoofing

Acts on Ch.1: CAN Bus

Threatens + TS.7

Mitigated by <no controls>

Prepared by AS.2

Attack Feasibility

- Employee** ^FeasibilityModel (BIExample.MethodConfiguration)
- Inside** ^FeasibilityModel (BIExample.MethodConfiguration)
- Outside** ^FeasibilityModel (BIExample.MethodConfiguration)

Accumulated	Ex2	T3	W2	K3		Low
--------------------	-----	----	----	----	--	-----

Risk Level

}

Note that only one feasibility model per attack tree is allowed and during the Risk Level calculation only the Feasibility Options of the selected feasibility model are considered.

If multiple feasibility models exist in a project there will be one risk matrix for each feasibility model in the Risk Model.

Note: This is not required by the ISO/SAE 21434 and is an advanced feature for complex method configurations. For most Security Analyst users, we recommend keeping the configuration simple and starting with just a single feasibility model.

Impact Levels per Stakeholder

A new expert feature for defining impact levels per stakeholder is added in this new release. If all Impact Levels in the Impact Model are prefixed with a Stakeholder's name, this new feature is implicitly enabled.

Impact Levels

The stakeholder prefixes are used to only consider the corresponding levels when turning a number into a level for a specific stakeholder.

For general calculation, the upmost matching interval will be used

RU.Neg : RU.Negligible	= 0	(when $0 \leq IL < 0$)
RU.Mod : RU.Moderate	= 1	(when $1 \leq IL < 1$)
RU.Maj : RU.Major	= 2	(when $2 \leq IL < 3$)
RU.Sev : RU.Severe	= 3	(when $3 \leq IL < 10$)
OEM.Non : OEM.None	= 0	(when $0 \leq IL < 1$)
OEM.Low : OEM.Low	= 1	(when $1 \leq IL < 2$)
OEM.Med : OEM.Medium	= 10	(when $10 \leq IL < 80$)
OEM.Hig : OEM.High	= 80	(when $80 \leq IL < 1000$)
OEM.Cri : OEM.Critical	= 1000	(when $1000 \leq IL$)

In this mode the same value can be assigned to multiple Impact Levels, e.g. OEM.Non = 0 and RU.Neg = 0.

To best utilize different treatments of the Stakeholder-specific Impact Levels, a custom impact option aggregator is needed. If this feature is enabled, you will see one Risk Matrix per Stakeholder in the Risk Model.

Note: This is not required by the ISO/SAE 21434 and is an advanced feature for complex method configurations. For most Security Analyst users, we recommend keeping the configuration simple.

Custom Factors

In the Risk Model you can now define custom factors within custom impact aggregators and use these for defining your own expressions. These expressions are identified by names and define multiple levels, each level being a double value.

In the ProjectInfo of the Analysis you can then reference the custom factor and select the active level. This allows you to control the calculation results from outside the Method Configuration (Risk Model), e.g., depending on your TARA's project phase.

Note: This is not required by the ISO/SAE 21434 and is an advanced feature for complex method configurations. For most Security Analyst users, we recommend keeping the configuration simple, which does not require custom aggregators at all.

Various fixes and improvements

- Change default project location from "MPSProjects" to "SECUREprojects"
- Renamed "Damped by" in Threat Scenarios to "Lessened by"
- Risk calculation caches are now cleared when switching branches
- New check that at least one stakeholder exists and improved error message in impact model if there is no stakeholder defined
- Update and improve tooltips in assistants
- Aligned the provided example's feasibility categories with ISO/SAE 21434
- XSAM: the serialization-name for SecurityControl changed to *Control*; for the import the old name "SecurityControl" is still supported
- Improved Security Objective to Threat Scenario migration
- Preparations for simplified threat scenario usage: Stay tuned!

Version Mapping

The following table can be used to determine the Security Analyst version based on the internal plugin version "com.moraad.core" that is stored in the .msd file of every solution:

```
<language slang="1:2bca1aa3-c113-4542-8ac2-2a6a30636981:com.moraad.core" version="<com-moraad-core-version>" />
```

com.moraad.core version	Security Analyst version
80	22.2
78	22.1
74	21.3
73	21.2
72	21.1.1
71	21.1
64	20.4
63	20.3.1
61	20.3
59	20.2.1
58	20.2
55	20.1.1
54	20.2.1
49	19.4.1
48	19.4
46	19.3.1
44	19.3
41	19.2
37	2.5.1
